Inter-process communication (IPC)

Kartik Gopalan

Chapter 2 of Tanenbaum's book

Chapter 4 and 5 of OSTEP book

Some simple forms of IPC

- Parent-child
  - Command-line arguments,
  - wait(…), waitpid(…)
  - exit(…)

- Reading/modifying common files
  - Servers commonly use 'pid' file to determine other active servers.

- Signals
  - Event notification from one process to another

Some more forms of IPC…

• Shared Memory
  - Common piece of read/write memory.
  - Needs synchronization for access

• Semaphores
  - Locking and event signaling mechanism between processes

• Pipes
 - Uni-directional (if used cleanly)
  - 'ps -aux | more'

• Sockets
  - Bi-directional
  - Not just across the network, but also between processes.
Pipes

Pipe Abstraction

- Write to one end, read from another

- pipe( )

fd[1] → **Pipe** → **fd[0]**

write( ) **read( )**

Pipe provides a byte-stream abstraction

- You can read and write at arbitrary byte boundaries.
  - E.g. Byte lengths sequence written
    - 10, 10, 10, 10
  - byte lengths sequence read
    - 5, 15, 15, 5

- As opposed to **message abstraction,** which provides explicit message boundaries.
 - E.g. network packets

# Parent-child communication using pipe

Parent

pipe( )

fd | 0 | 1 |

Here's an example.
http://www.cs.binghamton.edu/~kartik/examples/pipe1.c

Parent-child communication using pipe

Here's an example.
http://www.cs.binghamton.edu/~kartik/examples/pipe1.c

Parent-child communication using pipe

Parent —— fork( ) ——> Child

pipe( )

fd | 0 | ~~1~~ | fd | ~~0~~ | 1 |

Read end   Write end

Here's an example.

http://www.cs.binghamton.edu/~kartik/examples/pipe1.c

Filters in shell command-line
ps -elf | less

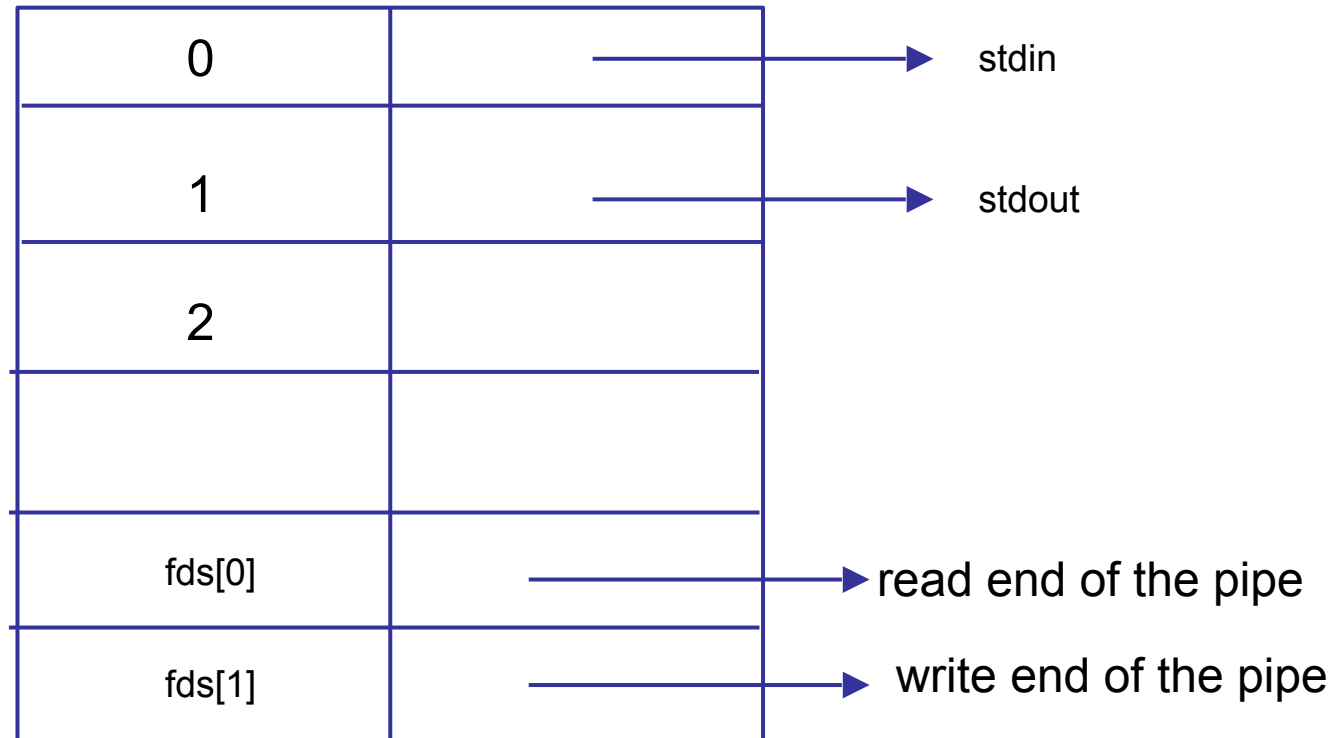

Here's an example.
http://www.cs.binghamton.edu/~kartik/examples/pipe2.c
Understanding fds: File-Descriptor Table

- Each process has a file-descriptor table
- One entry for each open file
- "File" = regular files, stdin, stdout, pipes, I/O devices etc.

0	→ stdin
1	→ stdout
2	
fds[0]	→ read end of the pipe
fds[1]	→ write end of the pipe

Handling long chain of filters — Recursive approach

- create a pipe
- fork a child
- redirect stdin and/or stdout as necessary
- fork another child for next level of recursion with a shorter command
- exec the command for the current level

Being careful with read()/write()

• read(fds[0], buf, 6);

- Doesn't mean read will return with 6 bytes of data!
- It could be less. Why?

• Some reasons

- read() could reach end of input stream (EOF).
- Other endpoint may abruptly close the connection
- read() could return on a signal.

• So you MUST incorporate error handling with every I/O call (actually with any system call)

Error handling…

- You must
  - First check the return value of every read(…)/write(…) system call.
  - Then either…
  - Wait to read/write more data OR
  - Handle any error conditions

More convinient to write a wrapper function

```c
/* Write "n" bytes to a descriptor. */
ssize_t  writen(int fd, const void *vptr, size_t n)
{
    size_t       nleft;
    size_t       nwritten;
    const char   *ptr;

    ptr = vptr;
    nleft = n;
    while (nleft > 0) {
        if ((nwritten = write(fd, ptr, nleft))<=0){
            if (errno == EINTR)
                nwritten = 0;  /* call write() again*/
            else return(-1);  /* error */
        }
        nleft -= nwritten;
        ptr   += nwritten;
    }
    return(n);

}
```
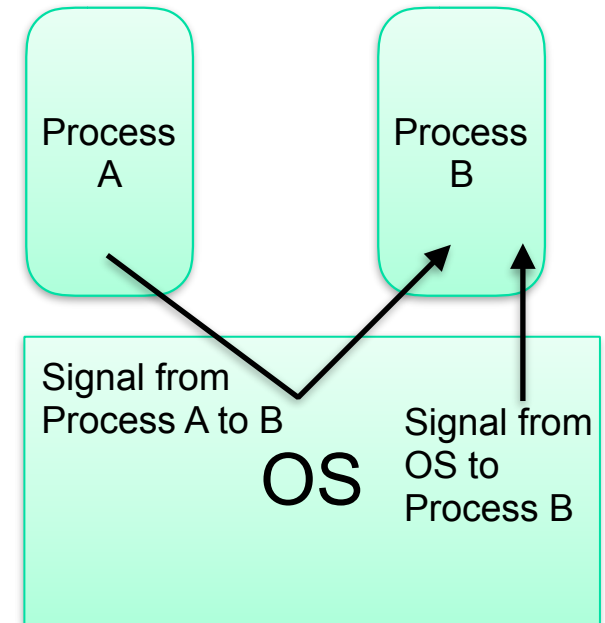

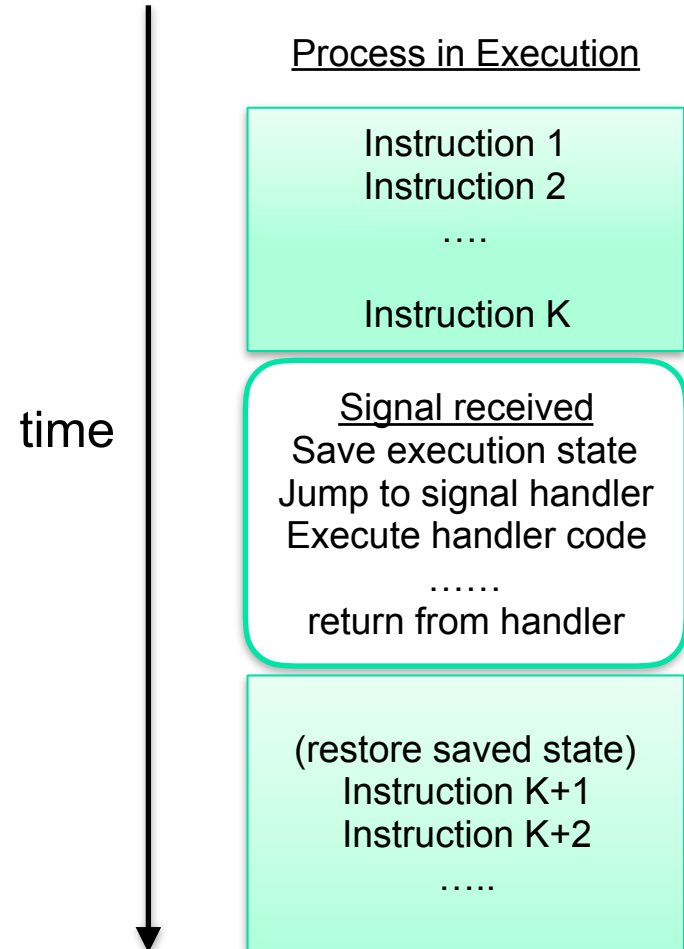

Signals

Signals Overview

- Signal is a notification to a process that an event has occurred.
  - Could come from another process or from the OS

- Type of event determined by type of signal

- Try listing all signal types using
  - % kill –l

- Some interesting signals
  - SIGCHLD, SIGKILL, SIGSTOP

Process
A

Process
B

Signal from
Process A to B

OS

Signal from
OS to
Process B

Handling Signals

- Signals can be <u>caught</u> – i.e. an action (or handler) can be associated with them
  - SIGKILL and SIGSTOP cannot be caught.
- Actions can be customized using
  - sigaction(…)
  - which associates a <u>signal handler</u> with the signal.
- <u>Default</u> action for most signals is to terminate the process
  - Except SIGCHLD and SIGURG are ignored by default.
- Unwanted signals can be <u>ignored</u>
  - Except SIGKILL or SIGSTOP
- Here's an example.
  - http://www.cs.binghamton.edu/~kartik/

Process in Execution

Instruction 1
Instruction 2
….

Instruction K

<u>Signal received</u>
Save execution state
Jump to signal handler
Execute handler code
……
return from handler

(restore saved state)
Instruction K+1
Instruction K+2
…..

time

More on SIGCHLD

- Sent to parent when a child process terminates or stops.

- If act.sa_handler is SIG_IGN
  - SIGCHLD will be ignored (default behavior)

- If act.sa_flags is SA_NOCLDSTOP
  - SIGCHLD won't be generated when children stop

- act.sa_flags is SA_NOCLDWAIT
  - children of the calling process will not be transformed into zombies when they terminate.

- These need to be set in sigaction() before parent calls fork()

Handling child's exit without blocking on wait()

- Parent could install a signal handler for SIGCHLD

- Call **wait(…)/waitpid(…)** inside the signal handler

```
void handle_sigchld(int signo) {
        pid_t pid;
        int stat;

        pid = wait(&stat); //returns without blocking

        printf("child %d terminated\n", pid);
}
```

- Here's an example.
 - http://www.cs.binghamton.edu/~kartik/examples/ sigchld.c

More information…

- Check 'man sigaction(…)'

- Understand what happens when signal is delivered in the middle of a system call?
  - Different OSes have different behavior.

- Google for keywords "Unix Signals"
  - Tons of useful links

Shared Memory, Semaphores

- Man pages : shmget, shmat, shmdt, shmctl, semget, semop, semctl

Shared Memory

Common chunk of read/write memory among processes

Creating Shared Memory

```
int shmget(key_t key, size_t size, int shmflg);

Example:
 key_t key;
 int shmid;

 key = ftok("<somefile>", 'A');

 shmid = shmget(key, 1024, 0644 | IPC_CREAT);
```

Here's an example.

http://www.cs.binghamton.edu/~kartik/examples/shm_create.c

Attach and Detach Shared Memory

```
void *shmat(int shmid, void *shmaddr, int shmflg);
int shmdt(void *shmaddr);

    Example:
        key_t key;
        int shmid;
        char *data;
        key = ftok("<somefile>", 'A');
        shmid = shmget(key, 1024, 0644);
        data = shmat(shmid, (void *)0, 0);
        // read or write something to data here.
        shmdt(data);
```

Here's an example.

http://www.cs.binghamton.edu/~kartik/examples/
   shm_attach.c

Deleting Shared Memory

```
int shmctl(int shmid, int cmd, struct shmid_ds *buf);

    shmctl(shmid, IPC_RMID, NULL);
```

Example:

http://www.cs.binghamton.edu/~kartik/examples/
shm_delete.c

Command-line IPC control

- ipcs
  - Lists all IPC objects owned by the user

- ipcrm
  - Removes specific IPC object
